

HRP-AI: A Web Application for Hypertension Risk Prediction with Calibrated Explainable AI

Jonathan Ralph F. Baes

practical issues limit the adoption of machine learning systems in clinical decision support. First, high-performing models such as gradient boosting ensembles are often considered black boxes, making

Abstract—Hypertension remains a major public health concern in the Philippines and requires scalable screening tools that are both interpretable and probability-aware. This paper presents HRP-AI, a web-based decision-support application for predicting clinical hypertension risk among Filipino adults using calibrated explainable machine learning. Using the 2015 DOST FNR National Nutrition Survey, a dataset of 151,189 adults was constructed including 22,988 hypertension-positive cases based on the $\geq 140/90$ mmHg clinical threshold. Eight machine learning algorithms were evaluated under multiple imbalance handling configurations using a two-stage randomized optimization strategy. XGBoost with class weights was selected as the final predictive engine because it provided the strongest clinical compromise between sensitivity, discrimination, and calibration compatibility. At the standard 0.50 decision threshold, the model achieved 76.87% accuracy, 76.51% recall, an F1-score of 0.5014, and an AUC of 0.8469. Under the selected 0.35 screening threshold, recall increased to 87.88%. Venn-Abers calibration reduced the Expected Calibration Error to 0.0035. The final pro_totype integrates calibrated risk estimates, uncertainty bounds, SHAP and LIME explanations, and Wachter-style counterfactual suggestions. The results show that non-linear machine learning models can be adapted into transparent, probability-aware, and exploratory hypothesis testing tools when discrimination, calibration, explainability,

their predictions difficult to interpret. Second, discriminative performance does not guarantee probability reliability; a model can rank patients well while producing poorly calibrated risk estimates. This is problematic in healthcare because risk scores are often interpreted as probabilities.

Explainable artificial intelligence (XAI) methods such as SHAP and LIME improve transparency by identifying the features that influence a prediction. Probability calibration methods such as Platt scaling, isotonic regression, and Venn Abers predictors improve the reliability of predicted probabilities. This study integrates these ideas into HRP-AI, a web application for hypertension risk prediction with calibrated explainable AI. The system is designed not as a replacement for clinical diagnosis but as an exploratory decision-support type for risk screening.

Abstract—Hypertension remains a major public health concern in the Philippines and requires scalable screening tools that can be used in resource-poor settings. This paper presents HRP-A1, a web-based decision support application for predicting clinical hypertension among Filipino adults using calibrated exponential machine learning. Using the 2015 DOST National Health Survey data, a 10-fold cross-validation was constructed, including 22,988 hypertension-positive cases based on the $\geq 140/90$ mmHg clinical threshold. Eight machine learning models were trained and evaluated using standard handling configurations using a two-stage randomized optimization strategy. XGBBoost with class weights was selected as the best model, achieving an AUC of 0.87, sensitivity of 0.85, and specificity of 0.86. The model achieved 76.8% accuracy, 70.5% recall, an F1 score of 0.73, and a negative predictive value of 0.82. The model's screening threshold recall increased to 87.88% when Bern-Berns calibration reduced the Expected Calibration Error to 0.0035. The model's performance was robust to model uncertainty, uncertainty bounds, SHAP and LIME explanations, and Wachter-style counterfactual suggestions. The results show that machine learning models can be used to predict hypertension, providing a scalable and interpretable tool for hypertension screening, probability-aware, and expository hyperparameter tuning when discrimination, calibration, explainability, and interpretability are required.
